1. SUMMARY OF 2018 RING OUZEL REPORT

- 1. First arrival at Nab Scar on 24th March; 2 days later than 2017 (5.2, Pg. 16)**
 - 2. 11 territories recorded in 2018; down a third from 2017 & well below 2012 peak of 23 (5.3, Pg. 16)**
 - 3. Mean of 3 fledged young for each laying pair in 2018; slightly below average (5.4, Pg. 26)**
 - 4. Productivity below long-term average in 6 of the last 7 years (5.4, Pg. 26)**
 - 5. Just over half (54%) of breeding pairs had a late nest; equal to long-term average (5.5, Pg. 27)**
-

2. INTRODUCTION

The 2018 survey was the 19th year in which a detailed study had been made of the Ring Ouzel *Turdus torquatus* (RZ) population in the North York Moors National Park; only the foot and mouth outbreak in 2001 and the subsequent closure of the moors, preventing what would have been 20 years of continuous study since the start of the project in 1999.

The findings of these studies were submitted to various bodies including the North York Moors National Park Authority, the RSPB Ring Ouzel Study Group, Natural England (York office) and the land-owners and head keepers of Spaunton and Rosedale estates.

As in previous years the 2018 survey concentrated mainly on recording Ring Ouzel activity in the Rosedale area of the North York Moors; an area of around 25 square kilometres. Reports of Ring Ouzel sightings in other parts of the National Park have been included with their approximate location shown on a map of the area. Sightings of birds that are considered to be passage migrants that appear annually across the Moors and along the coast have been excluded from the map.

A topographical map of the Rosedale area has been included for the first time. This shows the approximate location and name of the 40 or so territories referred to in the report.

Finally, as in previous years, the north-west and east side of Rosedale was surveyed by Vic Fairbrother and the west side south to Spaunton moor by Ken Hutchinson.

3. METHODOLOGY

3.1 Breeding Status Criteria

The criteria used to determine the existence of a territory is shown in the table below using the categories defined by the British Trust for Ornithology (BTO) for determining breeding evidence.

BREEDING STATUS	CRITERIA
Possible	<ul style="list-style-type: none">• Single bird observed in suitable nesting habitat.• Male seen or heard singing on one survey date only.
Probable	<ul style="list-style-type: none">• Male observed singing on two different days in a week or more at the same place.• Territorial behaviour observed on two or more days.• Pair observed in suitable nesting habitat.• Nest-building activity.• Agitated behaviour.
Confirmed	<ul style="list-style-type: none">• Nest found with eggs or chicks.• Recently fledged young seen.• Adult seen carrying food.

3.2 Fledging Criteria

An assessment of whether a brood fledged successfully is made using the ‘outcome success’ criteria of the BTO Nest Record Scheme as appropriate.

- Young fledged nest on approach.
- Fledged young near nest.
- Adult carrying food to fledged young near nest.
- Adult visibly agitated/alarming as if fledged young are near nest.
- Nest empty and undisturbed with well-trodden lining, containing feather scale and/or droppings.
- Young capable of leaving nest on penultimate visit.

Ring Ouzel chicks remain relatively settled when in the nest but can ‘explode’ from the nest when approached close to fledging. For that reason, nests are not generally inspected the day before the estimated fledging date in order to avoid this premature fledging.

In view of this and unless there is evidence to the contrary, such as obvious signs of predation, all nestlings present on the penultimate visit are considered to have fledged if the nest is empty on the later final visit.

The discovery of small groups of droppings in sheltered locations in the vicinity of the nest has also been noted as supporting evidence that fledglings have been hidden there for a time after leaving the nest.

3.3 Definition of Study Area

References in this report to the **Rosedale area** include the main dale (valley) of Rosedale and adjoining Spaunton Moor (Loskey Ridge, Loskey Side, Spaunton Knowl, Spindle Thorn). References to **Rosedale** refer only to the main dale of Rosedale.

4. RESULTS

1). Only a partial survey was carried out in 1999. 2). Foot & mouth prevented field-work in 2001. ✓ = occupied by pair * = not occupied ? = not checked																					

4.1.2 Other Areas of the North York Moors

The map at **Annex 2** shows the approximate location where Ring Ouzels were recorded on the North York Moors in 2018 - other than the Rosedale area and passage migrants.

4.2 Nest Sites

Table 2: Summary of Ring Ouzel nest sites monitored in 2018.

No.	Location	Grid Ref.	Outcome	Comment
1.	Rosedale west - Round Hill west	SE69249707	2 Fledged	1 st nest (early).
2.	Rosedale west - Round Hill west	SE69289705	3 Fledged	2 nd nest (late).
3.	Rosedale west - Round Hill east	SE69449672	Likely predated	1 st nest (early).
4.	Rosedale east - Reeking Gill cutting	NZ68860067	4 Fledged	1 st nest (early).
5.	Bransdale - Ousegill	SE63979470	3 Fledged	2 nd nest (late).

Further details of Rosedale territories and nests can be found in sections: 4.5, 4.6, 5.3 and Annex 3 and 4.

4.3 Annual Breeding Results

Table 3: Summary of annual breeding results at Ring Ouzel nest sites in Rosedale and other areas of the North York Moors between 2000 and 2018. (Detailed results are presented at **Annex 3**)

Year	Nests Monitored	Successful nests	Laying pairs (2 nd clutch)	Pairs that hatched young (2 nd attempt) [2 nd brood]	Pairs that successfully fledged young (2 nd attempt/brood)	Pairs that failed to fledge young	Total young fledged	Mean fledged young per successful nest ^a	Mean fledged young per laying pair ^b
1	2	3	4	5	6	7	8	9	10
00	1	1	1	1	1	0	4	4.00	4.00
02	1	1	1 (1)	1 (1)	1 (1)	0	4	4.00	4.00
03	7	3	6 (1)	4 [1]	3	3	11	3.66	1.83

12	13	7	11 (5)	6 (1)[3]	6 (2)	5	23	3.28	2.09
13	16	13	10 (6)	9 (1) [6]	9 (5) ^f	1	40	3.08	4.00
14	20 ^g	11	15 (5)	12 (1)[3]	10 (2)	5	40	3.64	2.86
15	13	9 ^h	12 (3)	9 (2) [1]	8 (3)	4	27	3.00	2.25
16	6	9 ^h	9 (3)	9 [3]	8 (3)	1	23	2.56	2.55
17	12	9 ^h	10 (5)	9 (1) [3]	8 (3)	2	30	3.33	3.00
18	5	4	4 (2)	4 [2]	3 (3)	1	12	3.00	3.00
Overall Mean								3.58ⁱ	3.11
Note									
a. Mean fledged young per successful nest (Column 9) = Column 8 ÷ Column 3									
b. Mean fledged young per laying pair (Column 10) = Column 8 ÷ Column 4									
c. A pair had two unsuccessful attempts before being successful at the third attempt.									
d. A pair had one unsuccessful attempt before being successful at second attempt.									
e. A pair had two unsuccessful attempts; 1 st was predated at the chick stage, 2 nd at the egg stage.									
f. A pair had four nests; 1 st was abandoned, 2 nd was predated at egg stage, 3 rd & 4 th were successful.									
g. The outcome of two nests located in Esklets is unknown as no final visit was made.									
h. Also includes nests that were not located but where recently fledged young were seen or where adults were seen feeding hidden young									
i. Mean: Glen Esk (Burfield) 3.48; Moorfoots (Burfield) 3.50; Yorkshire Dales (Appleyard) 3.60; BTO Nest Records (Flegg & Glue) 3.60.									

Interpreting Table 3

- Column 2 shows the total number of nests found and monitored that year.
- Column 3 shows the number of nests fledging young (i.e. successfully leaving the nest) that year.
- Column 9 shows the average number of young fledged from each nest that year (see Note i. for comparison with other study areas).
- Column 10 shows the number of young fledged per pair averaged for all the pairs that laid eggs that year and includes those pairs that abandoned their eggs, lost nests to predation or had infertile eggs. **This is a measure of productivity.**

The nests of four pairs were located and monitored in 2018, noticeably down on previous years reflecting the lower number of pairs recorded this year. The Round Hill west pair had an early and late nest in the cutting, the late nest being on the east side of the cutting the first time that the east side had been used over the years of the study. The five nests that were monitored have been used to determine annual productivity.

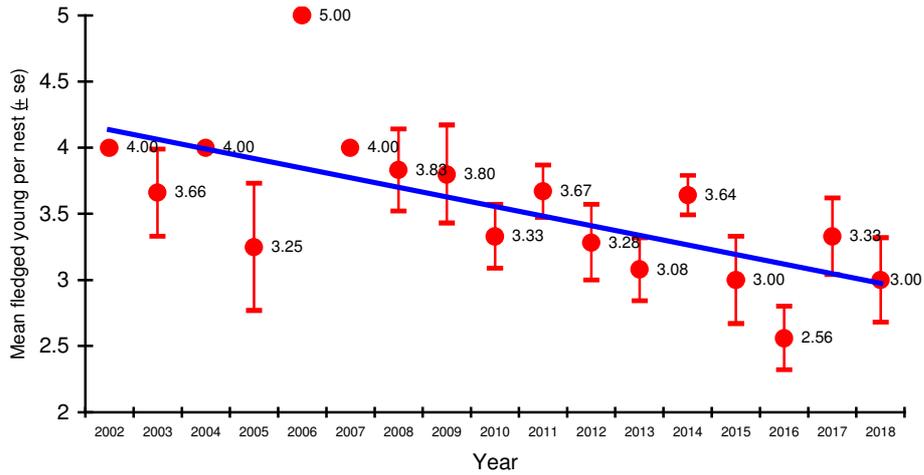

Figure 1: Annual mean fledged young per successful nest for Rosedale and other areas of the North York Moors between 2002 and 2018 showing 17-year trend.

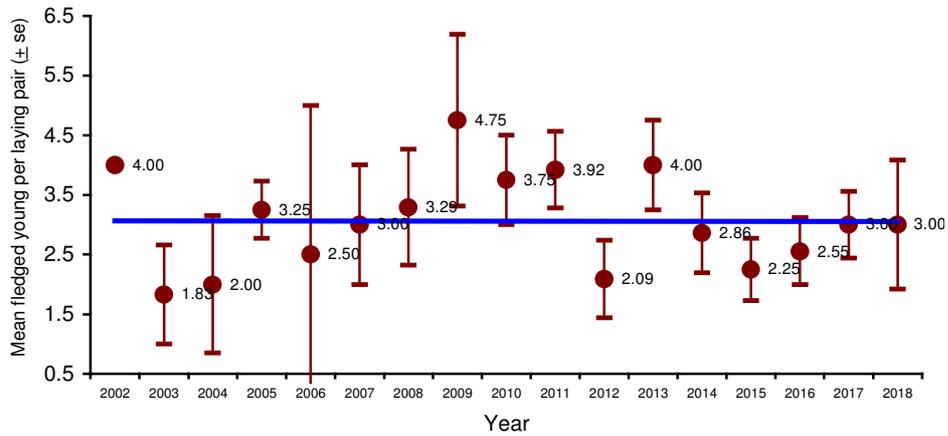

Figure 2: Annual mean fledged young per laying pair for Rosedale and other areas of the North York Moors between 2002 and 2018 showing 17-year trend.

4.4 First-egg Laying Dates

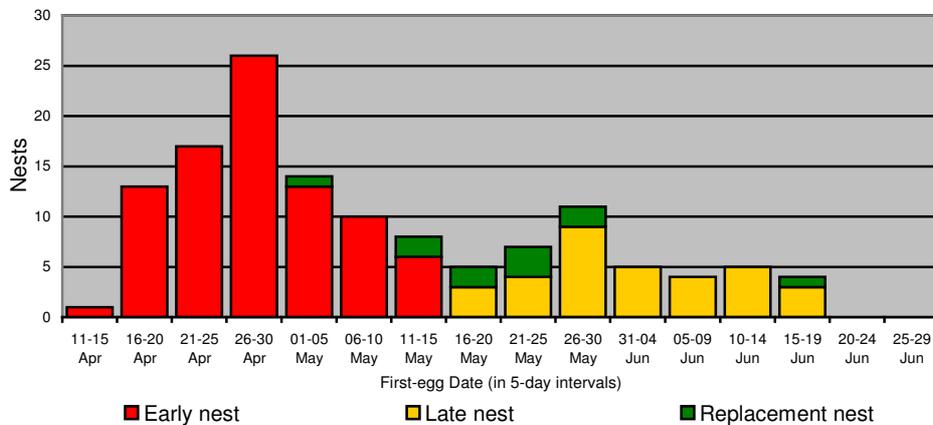

Figure 3: First-egg laying dates for Rosedale and other areas of the North York Moors between 2000 and 2018. Date points in 5-day intervals from April to June. (n=130)

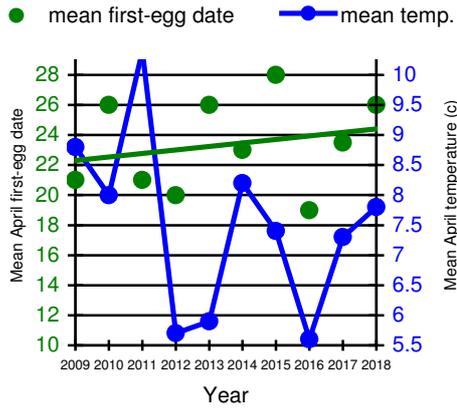

Figure 4: Mean April first-egg date and temperature for the North York Moors for the period 2009 to 2018 showing first-egg date 10-year trend (weather data from Fig. 6)

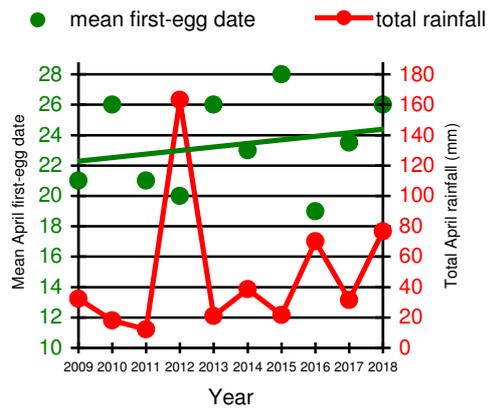

Figure 5: Mean April first-egg date and total April rainfall for the North York Moors for the period 2009 to 2018 showing first-egg date 10-year trend (weather data from Fig. 6)

4.5 First-egg, Hatching & Fledging Dates

Table 4: First-egg, hatching & fledging dates for Rosedale and other areas of the North York Moors.

Year	Nest location	1 st Egg	Hatching	Fledging	Comments
2000	Spaunton Moor	6 May (a)	21 May (a)	3 June	
2002	Bank Top	17 May	1 June	15 June	Replacement nest/eggs.
2004	Matty Carr Hill	26 April	11 May	25 May	
	Hob Crag	10 June (a)	26 June (p)	-	2 nd nest.
2006	Ousegill Bridge	10 May	25 May	7 June	
	Sheriff's Pit south	21 May	5 June	18 June	Replacement nest/eggs.
2007	Round Hill south	5 May (a)	20 May (a)	2 June (a)	
	Hob Crag	5 May (p)	-	-	
	Reeking Gill west	26 April	11 May	24 May	
	Dalehead west	29 April	14 May	27 May	
2008	Sturdy Bank 1 st	29 April	14 May (a)	27 May (a)	
	Sturdy Bank 2 nd	10 June	25 June (a)	9 July (a)	1 st egg 14 days after 1 st nest fledged.
	Round Hill south	1 May	16 May (a)	29 May	
	Reeking Gill	5 May	20 May (a)	2 June	
	West Gill	25 April	10 May	23 May	Seen copulating on 22 April.
	Hob Crag 1 st	28 April	13 May (p)	-	
	Hob Crag 2 nd	27 May (p)	-	-	Replacement nest/eggs.
	Sheriff's Pit	7 May	22 May	4 June	
	Dalehead north	25 May	9 June (a) (p)	-	Likely replacement nest/eggs.
2009	Reeking Gill	16 April	1 May	14 May	Pair arrived in gill on 25 March.
	Sturdy Bank	13 May (a)	29 May (a)	11 June (a)	Pair arrived in gill on 26 March.
	Round Hill south	26 April	11 May	24 May	1 st nest. 2 nd nest at Sheriff's Pit.
	Dalehead west	10 May	25 May	8 June	Likely to be 1 st nest.
	Sheriff's Pit	26 May	10 June	23 June (a)	2 nd nest. 1 st nest at Round Hill south.
2010	Sturdy Bank 1 st	30 April (a)	16 May (a)	29 May (a)	1 st nest.
	Sturdy Bank 2 nd	16 June (p)	-	-	Predated at egg stage.
	Reeking Gill	16 April	1 May	14 May (a)	1 st nest.
	Reeking Gill cut. 1 st	9 May	24 May (a)	6 June	1 st nest.
	Reeking Gill cut. 2 nd	11 June	26 June	7 July	2 nd nest. Likely fledged at 11 days.
	Ousegill 1 st	28 April	13 May (a)	26 May	1 st nest.
	Ousegill 2 nd	2 June	17 June (a)	-	2 nd nest. Failed at chick stage.
	Hob Crag 1 st	29 April	14 May	28 May (a)	1 st nest. Fledged at 14 days.
	Hob Crag 2 nd	9 June	24 June	7 July	2 nd nest
	Sheriff's Pit	13 May	28 May	10 June	Likely to be 1 st nest.
	Round Hill central	27 April	12 May	25 May	1 st nest.
	Dalehead quarry west	22 May	6 June	19 June	Likely to be 2 nd nest.

	Matty Carr west	21 April	6 May	18 May (a)	1 st nest. 4 pulli 13/5 est. 8 days old. Fledged: 2 on 18/5 & 2 on 19/5.
	Loskey Side	12 June	27 June	9 July (a)	2 nd nest. 4 eggs 19/6 & 21/6. 4 pulli 29/6 est. 2 days old.
	Round Hill west	19 June	4 July	17 July	2 nd nest. 3 eggs 24/6. 1 pullus & 2 eggs 4/7. 2 pulli on 14/7.
	Dalehead west	29 April	14 May	27 May	1 st nest. 3 pulli 22/5 est. 8 days old. Food taken to nest 26/5. Nest empty 30/5.
	Reeking Gill	20 May	5 June	-	Likely replacement nest. 5 eggs 3/6. 5 pulli 7/6 est. 2 days old. Found dead 9/6
	Hob Crag west	20 June	-	-	2 nd nest. 4 eggs. Found nest destroyed on 27/6 with eggs crushed.
	Farndale east – High Blakey	26 April	11 May	24 May	1 st nest. 4 eggs seen 1/5. 2 pulli est. 9 days old seen on 20/5.
2018	Round Hill east	25 April	10 May (p)	-	1 st nest. 4 eggs on 3/5. 2 day old pulli & 2 eggs on 10/5. 3 pulli 8 days old colour ringed on 18/5. Nest found empty 24/5, most likely to have been predated.
	Round Hill west 1	27 April	12 May	24 May	1 st nest. 4 eggs on 10/5. 3 four-day old pulli & 1 egg on 16/5. 2 pulli 6 days old colour ringed on 18/5. Likely fledged at 12 days.
	Round Hill west 2	5 June	20 June (a)	2 July (a)	2 nd nest. 3 one-day old pulli & 1 egg on 21/6. 4 pulli 7 days old colour ringed on 27/6. 4 pulli in nest on 28/6. 3 fledged 2/7 at 12 days. 1 found dead just behind nest, likely died day after ringing.
	Reeking Gill cutting	4 May	19 May (a)	3 July	1 st nest. 4 eggs on 10/5. 3 newly hatched pulli & 1 egg on 19/5. 4 pulli 5 days old on 24/5. 4 pulli 7 days old colour ringed on 27/5.
	Bransdale - Ousegill	27 May	11 June	24 June	2 nd nest. 4 eggs on 10/6. 3 two-day old pulli on 13/6. 3 pulli 10 days old on 21/6.

(a) = actual (o) = outcome unknown (p) = predated/abandoned

Dates other than actual are based on a 29-day breeding cycle assuming female commences sitting on 3rd egg and both incubation and chick stage take 13 days.

4.6 Distance Between First & Second Nests

The distance between first and second nests is shown below in Table 5. Most built their second nest close to the first. The exception to this was the 2009 pair that moved more than half a kilometre to build their second nest - the female's distinct white head marking easily identified the pair. Studies by Appleyard in the Yorkshire Dales record a mean distance between first, second (third) brood nests of **64** metres with a median of **55** metres (n=26). For the North York Moors the mean and median values are **92** metres and **62** metres respectively (n=30).

Table 5: Distance between 1st and 2nd nests in Rosedale and other areas of the North York Moors.

5. DISCUSSION

5.1 Climate

5.1.1 Local Weather Observations

March The dominant feature of the March weather was the so-called “Beast from the East”. This was the name given by the Met Office to a blast of cold easterly air that brought snow and sub-zero temperatures to most parts of the country on three separate occasions throughout the month. The first event saw some 20cm of snowfall over the higher grounds of the Moors on the last day of February that lasted until the fourth of March. Further occurrences on 16th and 28th of the month saw cold easterlies return with temperatures struggling to get above freezing by day. These events saw winds gusting up to 45mph making for temperatures that felt more like the Arctic. By the last two days of the month the wind eased and moved round to the west, bringing unsettled wet conditions and over 20cm of rainfall on the night of the 31st.

April The start of the month continued unsettled with over 24mm of rain falling on the 1st and for a good part of the following day. Winds during this period were strong and gusty, though daytime temperatures were into double figures with no frost at night. Towards the middle of the month a strong easterly airflow brought fog to inland locations making visibility poor. This persisted from the 10th to the 13th before a change of wind direction brought milder air from the south. By the 18th daytime temperatures across the moors started to climb to the high teens and by the 19th records were being broken across much of the UK with mid-day temperatures recorded at the Westerdale weather station reaching 23c. Overnight temperatures during this period remained in double figures. Rainfall recorded at Westerdale during the first half of the month exceeded 70mm, though drier conditions returned towards the end of the month. Temperatures dropped sharply in the later part of the month with daytime highs struggling to reach double figures and overnight temperatures dropping close to freezing. By the last day a strong gusty northerly airflow had set in making for cold conditions.

May After an unsettled start to the month, temperatures started to climb with day-time highs in the low twenties. Records across the UK were broken with the May Bank Holiday weekend of the 5/6th being the hottest on record. The 8th saw the end of the hot spell with temperatures returning to a more seasonal norm in the low to mid teens. Little rain occurred during the first half of the month. The dry conditions continued through the second half with the *Extreme Fire Risk* notices put out on the moorland roads in the last week of the month. Day-time temperatures by the end of the month climbed into the low twenties with night-time values staying in double figures. A feature of May was the strong gusty winds that occurred through throughout most of the month. Gusts recorded at Westerdale in the early part of the month exceeded 40mph, while gusts of up to 20mph were recorded on several days throughout the month. On the closing day of the month the temperature topped 24c. Across the UK it was the warmest May since records began.

June Saw more settled conditions with little rainfall. The gusty conditions recorded in May continued on and off throughout the month with peaks in excess of 40mph recorded over-night on the 13/14th. Temperatures fluctuated markedly throughout the month with highs on some days exceeding 20c while on others they struggled to reach 12c. By the last week a high-pressure system had established itself over the British Isles bringing hot conditions with temperatures locally reaching the mid-twenties by day. By the end of the month the *Extreme Fire Risk* signs had been put out again, reflecting the dry parched conditions that had resulted from a long absence of any significant rainfall.

July The hot dry conditions continued throughout July with mid day temperatures most days exceeding 20c, although slightly cooler conditions returned briefly during the second week. By the middle of the month less than 15mm of rainfall had been recorded over the past 45 days, making for extremely dry parched conditions across the Moors. Unsettled conditions returned in the closing days of the month with winds gusting to 40mph and close to 50mm of rain falling between the 27th and 29th. The end of the month saw the hot dry conditions return with day-time temperatures again exceeding 20c.

Graphs of temperature and rainfall for the months March to July 2018 recorded at Westerdale, North York Moors, are shown at Annex 5. Figure 6 charts the mean temperature and total rainfall for the month of April for the years 2009 to 2018 at Westerdale, while Figure 7 charts the regional mean temperatures and rainfall for the years 2001 to 2018.

The Westerdale weather station is about 180 metres a.s.l. near the village of Westerdale (NZ6605) on the North York Moors and is approximately five km north-west of Rosedale dalehead.

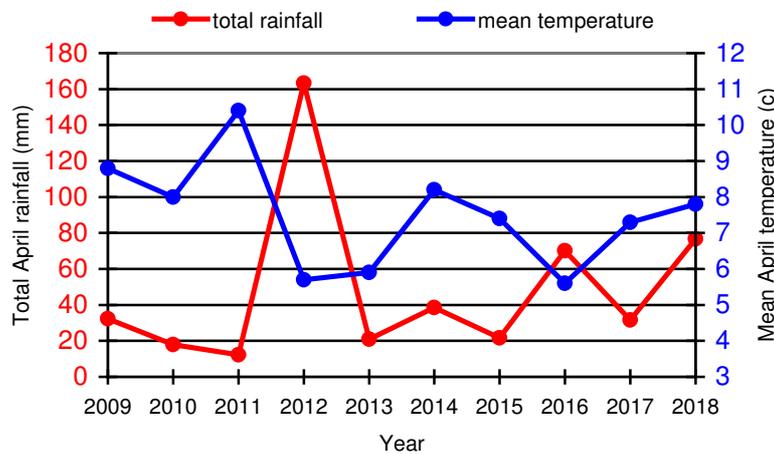

Figure 6: Mean temperature and total rainfall for the month of April recorded at Westerdale, North York Moors, between 2009 and 2018.

5.1.2 Regional Values

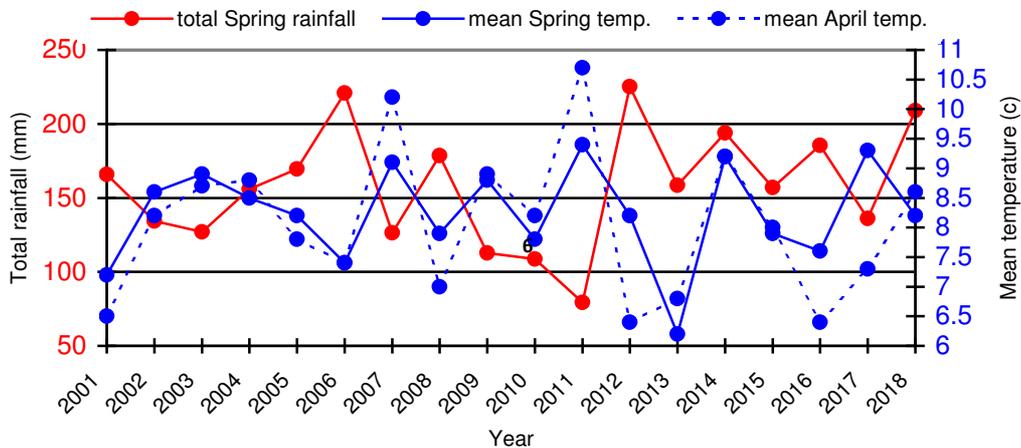

Figure 7: Spring and April mean temperatures and total rainfall between 2001 and 2018. (Data for Met Office North-East England Region. Spring = March, April, May)

5.2 First Arrivals

Rosedale was monitored for first arrivals from the beginning of the second half of March. The first Ring Ouzel to be recorded in the dale in 2018 was a single male on the east side at Nab Scar on **24th March**. On **1st April** a male and female were seen feeding together in the meadow at Round Hill south; the first female recorded in 2018. Further sightings were reported of two at Bank Top on **2nd April** and three at East Mines on **5th April**.

By **6th April** a male was seen at Sheriffs Pit, three at Bank Top and two in the Hob Crag area - one with a Yellow ring (see 5.3.7). Also on **6th April** the first singing male was heard at Bank Top by the cottages. On **9th April** a male and female were seen feeding just below the track at Nab Scar south and later in the day five (inc. three male and one female) were seen feeding at the south end of Nab Scar south.

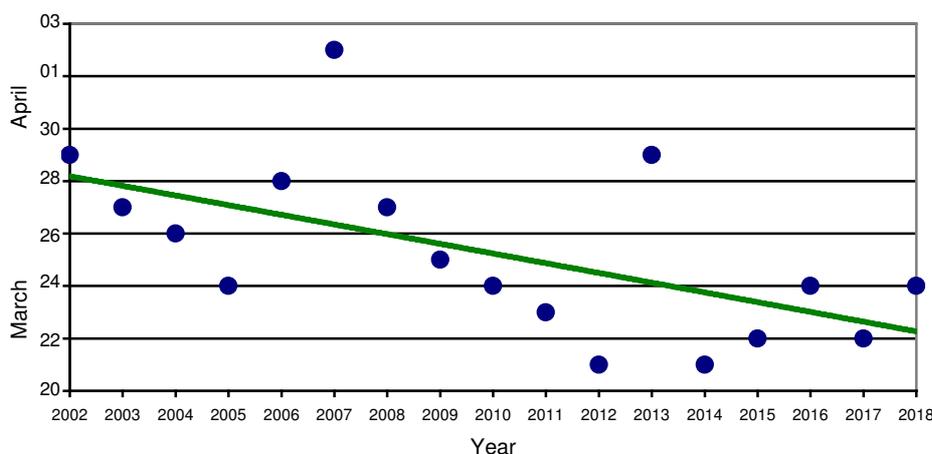

Figure 8: First-arrival date and 17-year trend for the Rosedale area of the North York Moors for the period 2002 to 2018.

5.3 Rosedale Territories and Nests

Eleven Ring Ouzel territories were recorded in 2018 in the Rosedale area of the North York Moors; six less than 2017 representing a drop of around a third on last year. All territories recorded in 2018 had been occupied before in previous years. Despite several visits to Spindle Thorn and a single visit to Loskey Side ford on Spaunton Moor, where a nest was located in 2017, there were no signs of activity at either location.

As in the previous two years an unexplained situation was the low number of territories recorded again on the east side of Rosedale. For several years the north-east side of the dale was a much-favoured breeding area with the Reeking Gill area having the highest breeding density in the dale – typically 3 pairs/km² against an average of 0.47 pairs/km² for the Rosedale area in general. The reason for the decline over the last three years on the east side of the dale and the apparent move to the west side is unclear as there had been no notable change to the habitat on the east side.

One of the most striking features of the Rosedale study is the remarkable close association of nest sites with the rich industrial heritage. The disused quarries, railway track, cuttings and mine shaft providing over half, 56 per cent, of the locations chosen by Ring Ouzels to build a nest (see Figure 11). Another surprising feature is the growing number of nest sites on relatively level ground on the moor tops, accounting for eight per cent of the total nest sites recorded.

The past 20 years of the Rosedale study has clearly shown the Ring Ouzel to be an adaptable bird when looking for a suitable site for a nest and is prepared to include man-made features in its selection of suitable breeding habitat.

In all, 44 distinct territories have been recorded in the Rosedale area between 1999-2018 (see Table 1). The location of the 2018 territories is shown at **Annex 1**.

5.3.1 Bank Top

The first sighting here was on **6th April** when two males and what was thought to be a female were seen on top of the kilns at Bank Top; one heard singing a short burst of simple song. On **18th April** a good audio recording was made of a male singing in the singleton tree near the cottages at Bank Top. A sighting on **22nd April** of a male and female feeding by the trackside just east of Hob Crag quarry and then flying off in the direction of Three Howes to the west of Bank Top, was reported by a member of the Scarborough Field Naturalists on their outing to Rosedale.

On **5th May** a male was seen foraging on the moor-side of the intake wall 100m east of Hob Crag quarry. It was then seen flying over the moor in the direction of Three Howes behind Bank Top kilns. There were no further sightings until **12th June** when the under-keeper reported seeing a male along the track between Bank Top cottages and the road; close to where a nest was found in 2016. Further sightings in the same location, of what was assumed to be the same male, were made on several days around the 12th. A visit to the area on the **13th June** found no sign of activity in an hour's observation.

A further report by the under-keeper around this time of a male collecting food near the track leading from the road to Ana Cross was thought most likely to be the same bird seen on **12th June**. On **24th June** there was a reported sighting of a pair of ouzels close to the roadside near a shooting butt just south of Bank Top car park. A wide search of the area on **26th June** found no ouzel activity.

Despite no nest being found there was sufficient activity in the Bank Top area throughout the season to record this as a Probable territory with an early and late nest.

5.3.2 Bank Top east

On **2nd April** a local resident reported seeing two ouzels above Bank Farm on Chimney Bank. Further sightings were made on **18th April** of three males and one female partway down the incline. A little later one was seen foraging on the incline while one flew towards the moor top above the incline where it was seen singing. A male and female were then seen flying off in the direction of Bank Top cottages; the male in pursuit of the female in what appeared to be an act of courtship. There was no further sighting until **5th May** when a solitary male was observed in the singleton tree half way down the incline. There were no further sightings after the 5th.

The incline has been a frequent stop-off place for passage migrants over the years of the study. It was thought likely that some of the early activity in this area were Fennoscandia passage birds and that these had attracted the attention of the resident Bank Top pair, the male of which was defending his territory.

5.3.3 Blakey Lion

There were few reports and there was no evidence of breeding here in 2018.

A male ouzel was reported in the garden opposite the Lion Inn on **11 May**.

On **19 May** a male was singing from a field fence post below the house opposite to the Lion Inn. He was then lost to view but singing was heard from low down on the moor below.

Blackbirds fledging young from a small pit near the fence line and north path slightly confused things. A male ouzel also sang from further north near the track side ruin.

5.3.4 Dalehead quarry

On **18 May** the quarry was observed from above at the south end. A male ouzel was sitting, not perched on top of the far bank, facing north. Another ouzel presumably the cutting male was singing from the wall that runs from the Cutting. After 15 minutes chacking was heard from below in the trees. A female ouzel then made a brief appearance below and a male sang somewhere in the north of the quarry while the other male was still on the far bank. All was then quiet for a while until a female ouzel flushed from on the heather below. She circled round at a good distance and the male disappeared from the far bank. A pair was then seen on the bank of the plateau near the track where he sang and she chacked. Ten minutes later both came back into the quarry, the male to the far bank, and the female into the trees below.

The quarry was watched from Dalehead west on the morning of **19 May** as a pair of ouzels fed at the north end of the quarry floor. The female flew south amongst rocks and out of view. The male continued to feed and then chased an intruding ouzel westwards before returning to resume feeding. He moved out of sight and later singing came from trees in the bottom of quarry at the south end. A pair of blackbirds feeding at the north end added to this confusion. An ouzel could also be heard singing in the distance somewhere in the Dalehead area. In the afternoon observation was continued from above the north end of the quarry. The sound of chacking eventually revealed a pair of ouzels feeding below in the quarry. It was decided to descend to the floor of the quarry at which she chacked south out of sight into rocks. Three ouzels then chacked out of the trees, two flying directly out of the east side of the quarry and the other remaining to sing from a tree at the south end. Intermittent singing continued from the south as well as chacking from trees on the eastern face. Later a male sang loudly and chacked from the oak tree near the large rock at the south end of the eastern quarry face. There was also chacking from trees on the eastern face at the north end. All this activity was frustratingly inconclusive but there would appear to be at least one territory in the quarry.

On **24 May** a male was heard singing in the quarry from Dalehead west. Later when viewing from above the south east end of the quarry a female flew in from the south west and chacked in to trees below and then went quiet. A male sang from the bottom of the quarry. After walking back to Dalehead west the female could be seen feeding in the middle of the quarry floor before eventually flying into trees at the north end. Sightings still indicate a nest at the north end of the quarry and possibly one at the south east edge.

At Dalehead faint simple song could be heard coming from the direction of the quarry on **9 June**. The descent to the quarry was made from the north and after ten minutes chacking could be heard from above on the northern cliff face. A female followed by the male flew down to feed on the quarry floor. On moving position to get a better view of the cliff above, after 12 minutes the female flew back and into one of the trees masking the cliff face and out of view. The male flew up into the isolated tree away from the cliff. The female was not relocated, the western half of the cliff face now being well screened by the growing trees. All remained quiet and the quarry was left. On return in the early afternoon the descent was made to observe from near the oak tree towards the south end. Blackbirds and a male Redstart were active and a Willow Warbler was singing. After a long wait there was chacking from behind and an ouzel flew into the trees masking the northern cliff face. 15 minutes later there was a sudden commotion and a Blackbird and Ring Ouzel made a joint attack on a Jay and drove it out of the quarry. In 2011 a nest was predated here and a Jay had been chased from the area on that occasion. After another 15 minutes the female flew down into the quarry to feed. It was not clear where she came from. The male then followed her down. After 12 minutes the female returned to land in the isolated rowan tree near the east end of the northern cliff face. She then dropped to the ground and was not seen again. The nest must be somewhere high on the cliff face. On approaching Dalehead a male Broad-bodied Chaser was active over a small pool on the track just north of the ponds. Chacking was heard from the top of the quarry at the north end on **5 July**.

The quarry is a difficult site to monitor but it was frustrating not to be able to locate the nest at the north end where there was so much activity.

5.3.5 Dalehead west

On **16 April** a pair of ouzels feeding close together just below the track flushed out of view towards the dale side mounds. They did not emerge when a couple of walkers passed through but a male later appeared in a tree at Dalehead. He remained silent while a Mistle Thrush sang for several minutes from the top of the same tree. Both flew off as another walker came through. The female was not relocated. There was no evidence of a territory being established here in 2018.

5.3.6 East Mines

Snow and hard frost still lingered early on the morning of **5 April** when three ouzels chacked out from just north of East Mines before flying across the dale towards Sledge Shoe and Middle Ridge. Three ouzels were also observed between the two sets of kilns on **9 April**.

On **23 April** a female flushed from the slope just below the track and in to broom. She chacked a couple of times and disappeared into the extensive broom and was not relocated.

5.3.7 Hob Crag quarry

On **6th April** a male ring ouzel was seen flying off the moor and landing some 200m east of Hob Crag quarry. The bird then foraged in the grassy area on the moor side of the intake wall for 15 minutes or so before slowly making its way towards the quarry. The bird was seen to have a **yellow** ring on the left leg but positive identification of the ring letters proved impossible owing to the distance; of note was that a yellow ringed bird was recorded in the same area in 2016 and 2017. The nearest nest to Hob Crag quarry where pulli were rung with yellow rings was on the moor plateau at Bank Top in 2015, some 500m south of the quarry. If this was the nest where this bird came from then 2018 would be the third breeding season for this male. Later in the day a second male was seen singing from a rock below the main part of the quarry then flying off into the dale-bottom and out of view.

There were no further sightings until **22nd April** when a member of the Scarborough Field Naturalists on approaching the quarry reported hearing an ouzel singing in the quarry. On entering the quarry a pair was observed in the main part of the quarry, the male having a **yellow** ring. On **5th May** what was likely the same **yellow** ringed male was seen singing from a large boulder below the main part of the quarry. The bird sang almost continuously from 1351 to 1415 hours with a mixture of simple and complex song before suddenly flying off and out of sight. A photo of the bird was taken in an attempt to read the lettering on the ring but unfortunately the strong sunlight reflected off the yellow ring making it impossible to see the black lettering - see front cover photo. This was the last sighting of the **yellow** ringed bird.

There was a further sighting on **16th May** when a lone female was seen feeding 50m east of Hob Crag quarry. She slowly made her way towards Bank Top before flying back over the quarry and on to the moor top out of view. On **31st May** a male was seen feeding two juveniles in the meadow just east of the quarry. One juvenile was seen standing under a rock overhang the other flying down a gully into the wooded area below the quarry. At the same time another ouzel was heard singing in the quarry. Analysis of the sonogram of this bird's song showed it to be the same ouzel recorded later in the day at Thorgill Bank quarry and was probably an unattached male looking for a female (see 5.3.17).

Further activity was recorded on **26th June** when a pair was observed in the main part of the quarry. A short while later the female was seen flying into the base of a tree growing out of a crack in the quarry wall. A closer inspection of the area flushed the female from a ledge high up behind the tree. The location looked to be a good nesting site but was inaccessible so a detailed inspection was not possible as a consequence no nest was found. The male during this time was close by chacking giving the impression that a nest was close. On **5th July** the quarry was observed for over an hour but with no sighting of the pair or any ouzel activity, the 26th June being the last recorded ouzel presence in the quarry.

5.3.8 Matty Carr quarry

The first sign of activity in the Matty Carr area was on **15th April** when an unsexed ouzel was seen flying along the dale-bottom from the direction of Matty Carr south towards the quarry. A look in the quarry found no sign of ouzel activity. On **26th April** a male flew from the north end of the quarry and dropped to ground in an area of deep heather 50m north-west of the quarry. Approaching the area the bird was flushed, flying off in the direction of the track cutting and out of sight. On **3rd May** a male flew in to the singleton tree at the south end of the quarry from the Matty Carr south direction in response to the lure. After chacking for a minute or so he flew back towards Matty Carr south and out of view. The male returned after 10 minutes landing in the same tree as earlier before flying off over the quarry and landing nearer the track before then flying off over the moor top and out of view. Checked previous year's nests in cutting and quarry but no sign of re-use.

On **10th May** the lure was used at the south end of the quarry. A male responded flying in from the direction of Matty Carr south and landing in the singleton tree at the south end of the quarry. The bird was seen to be carrying a small grub. After a few minutes the bird flew on to a clump of heather above the quarry before then returning to the same tree and then back in the direction of Matty Carr south and out of sight. On **24th May** a male was seen chacking in the singleton tree at the south end of the quarry. The bird was observed chacking continuously for over five minutes before swirling mist enveloped the area and brought matters to an abrupt end.

There were no further sightings after this date in the Matty Carr quarry area. See 5.3.9 below for comment on the breeding status in the Matty Carr area.

5.3.9 Matty Carr south

There were various sightings during the early part of the season of ouzels flying into Matty Carr quarry from the direction of Matty Carr south (see 5.3.8 above). A more detailed search of the area south of the quarry on **10th May** found no evidence of ouzel activity. On **7th June** a male was flushed from the trackside at the south end of Matty Carr south - SE 6895 9797 - and flew off chacking over the dale-edge into the dale-bottom and out of sight. This was the last sighting of activity in the Matty Carr south area.

The early activity in the Matty Carr quarry and south areas at the beginning of the season strongly suggests that a pair had an early nest that was most likely in the Matty Carr south area; though this was not found, there was sufficient evidence to record this as a Probable territory. The lack of activity after May points to there being no attempt at a second clutch in the Matty Carr area.

5.3.10 Nab Scar

The first Ring Ouzel contact of the year in the study area was here when chacking was heard on **24 March**. A lone male was located in a Rowan tree almost opposite the cairn. After more chacking as he faced the Scar he suddenly flew out over the cairn across the dale in the direction of Matty Carr.

A pair fed for about an hour in a field at the south end on the morning of **9 April** and were still present on returning in the early afternoon. Five more including at least one female were feeding south of the cairn before flying to Nab Scar North. There was some singing as well as chacking. Two flew high along the Scar summit in the early afternoon.

On **1 May** a male sang from a tree at the north end of the Scar. He dropped to the ground and sang from a boulder and was then lost to view on the ground. There was no further contact in the next hour during which a pair of Buzzards circled overhead before moving on and then a Sparrowhawk made a brief pass over the Nab. On returning to the site in mid afternoon a male was located feeding dale side of the track south of the cairn before eventually flying back to the tree at the north end of Scar. There was no chacking or any sign of female.

There was no evidence of a territory being established at Nab Scar and some of the early April sightings were probably of passage birds. Reports here and elsewhere of ouzels flying across the dale are perhaps significant as there have been more nests on the west side in the last two or three years.

5.3.11 Reeking Gill

There were no reports of territorial behaviour within the Gill but a pair bred successfully in the adjacent cutting (see 5.3.12).

A lone ouzel was in the second Rowan tree south of the gill on **9 April**.

5.3.12 Reeking Gill cutting

On **12 May** a Ring Ouzel was heard singing ahead as the Gill was approached at 12 noon. A male was located on the southern end of the track side fence at the end of the cutting. He sang for ten minutes and then dropped to the ground to feed moor side and then out of view. It was decided to descend and to watch and wait from a boulder moor side just north of the gill. He sang out of view for another 15 minutes even while walkers passed through. Then all was quiet until 13:00 when a movement was heard above and behind and two ouzels were seen to flutter up together and then a third ouzel appeared. The first two were males and they flew across the path and landed together close to the path dale side. While this was happening the third ouzel was glimpsed flying north along the cutting and into heather. The two males had a brief altercation and one gradually shepherded the other along the ground away from the cutting before it eventually flew off towards Nab Scar. Assuming the third ouzel was the female the point where she disappeared into the heather was fixed before the north end of the cutting was approached. During the return above the cutting the nest could now be seen on the north east side. The return was made back along the floor of the cutting from the north. The nest was just out of view until

the final couple of metres so sufficient noise of approach was made to ensure she flushed before a sudden appearance could startle her. She flushed at several metres and the nest quite exposed to view, was above head height and contained four eggs. On passing later in the day the female could be seen back on the nest incubating.

On **18 May** the female was watched on the nest for 35 minutes and then the male came in from the north and perched on top of the cutting nest side before working his way south softly singing. The female then flew off the nest and followed the male over the opposite bank and fence towards the dale side of the gill. In their absence the nest was quickly checked and it still contained four eggs.

The Cutting nest was approached from the north end on **19 May** and the female flushed south out of the cutting at about 10 m. The nest contained three newly hatched chicks and one egg.

On **24 May** the female was off the nest and on inspection it contained four sleeping chicks. Now five days old as one stirred the eyes were just opening. There was no sign of the adults. As the Cutting was approached on **27 May** a male was singing from somewhere just north of the quarry. The adults were not in the vicinity and a quick check of the nest revealed four chicks sitting tight. The rings were prepared out of sight of the nest before collecting and ringing the chicks with a yellow ring (ring letters: DA, DB, DC & DE). The female returned to the vicinity during the latter stages of ringing with some chacking but settled out of sight.

Rain was forecast so only a brief visit was made to check the nest on the morning of **2 June**. The male was located on the cutting fence as Reeking Gill was approached. He seemed agitated and there was no sign of the female on the nest or nearby. The male chacked up and down the cutting, frequently settling on the heather. Having retreated northwards for a while to let walkers pass through, when all was clear the cutting was entered and the nest was empty and undamaged. There was still no sign of the female and the behaviour of the male indicated the presence of fledglings nearby so the area was vacated as rain started. The cutting was deserted on **9 June** so the area was observed from track side just north of the gill. After a long wait, first one and then both adults emerged from ground cover. They were collecting food just below the track, dale side just beyond the gill. They were only occasionally in view for a period of about an hour and were obviously feeding fledglings which were well concealed. They were left undisturbed. A pair of Kestrels was active above the gill.

On arrival at the Cutting on **5 July** fledglings could be heard calling at the south end on the far bank amongst bracken and heather. Calls came from four different places about 30 m apart. During the next 20 minutes a male flew up on to the top between Reeking Gill and the Cutting and gave one round of simple song before disappearing into the heather. The fledglings continued to call periodically none showing themselves and there was no sign of movement. The impression was that these were recently fledged rather than the chicks which had fledged at the end of May and would by now have been expected to be much more active and mobile.

5.3.13 Round Hill east

On **26th April** a male was seen singing in a tree close to last year's nest site. After a few minutes it flew off down a nearby gully into the dale-bottom and out of sight. Later a male was flushed from the trackside between Round Hill east and Sheriff's Pit and flew a short distance along the track towards Sheriff's Pit before flying off in the direction of Round Hill south and out of view. Later in the day a male and female were seen flying from the direction of Round Hill south and landing on the track close to where the male had been observed earlier in the day. Both then flew off in the direction of Sheriff's Pit and out of sight.

The next sighting in this area was on **3rd May** when a male and female were seen in a tree in the dale-bottom at the north end of Round Hill east. After a few minutes the male dropped to the ground below the tree and out of view. The female remained in the tree for a further five minutes before flying off in a northerly direction out of view. A second male then flew into the same tree from the south end of Round Hill east but was then lost from view. A while later a male was seen singing in a tree close by and after a few minutes flew into a small track side quarry immediately above the tree and out of view. A look in the quarry flushed a female from a nest containing four eggs.

On **10th May** a male was seen singing in a tree just below the track and close to the quarry nest – an audio recording of the song was made. Checking the nest two newly hatched chicks

were seen and two un-hatched eggs. A further inspection of the nest was made on **16th May** when three pulli, estimated to be six days old, and one un-hatched egg were seen. Three pulli were ringed with a yellow ring on **18th May** (ring letters: CU, CX & CY).

A look at the nest on **24th May** found it to be empty. On close inspection the nest was found damaged, with a few outer stems of heather broken and the inner grass lining partially pulled out. Just outside the nest were around 20 soft feathers that could have been lost by one of the pulli while attempting to escape. The most likely turn of events was the nest was predated sometime after the 18th May when the chicks would have been eight days old. On a typical 13-day cycle the chicks would have fledged around the 23rd May in the normal course of events. It is just possible that the predator may have struck close to the fledge date in which case all three may have escaped, albeit one losing a few feathers in the struggle. However, the most likely scenario is that all three were taken, assumed by a ground predator, and that non-survived. This nest was recorded as predated.

On **31st May** a recording was made of a male seen singing in a tree close to the predated nest. Analysis of the sound recording made of this bird, and the one recorded in the same tree on the 10th May, showed them to be different males. A second male flew into a nearby tree close to the singing male and almost immediately flew off in the direction of Round Hill west closely followed by a female that had appeared from the direction of Round Hill south; thought most likely to be the pair from Round Hill west (see 5.3.14). On **7th June** an unseen male was heard singing from a tree close to the predated nest. A further sighting was made on **21st June** when two ouzels were seen flying from the Round Hill east area towards Sheriff's Pit. There were no further sightings in this area after this and no evidence of a replacement or late nest.

5.3.14 Round Hill west

The first sighting of activity in the Round Hill west area was on **26th April** when two ouzels, one male the other of unidentified sex, were seen in the singleton tree below the track at the north end of the Round Hill west cutting. The male remained in the tree chacking while the other flew off into the dale-bottom and out of sight. On **3rd May** a pair was seen foraging in the dale-bottom just above the intake wall; the female occasionally stopping to preen. Both were observed in the same area for over 15 minutes before being lost from sight. A further sighting was made on **10th May** when a male and female were seen feeding together below the intake wall. After 15 minutes the female flew up the side of the dale towards the track and into the north end of the cutting and out of sight. A short time later the cutting was searched and the female flushed off a nest containing four eggs. There was a brief sighting of the male at the south end of the cutting at this time.

On **16th May** the nest was inspected and three pulli estimated to be four days old and one un-hatched egg were seen. A further inspection of the nest on **18th May** found only two pulli in the nest; both were rung with a yellow ring (ring letters: CT & CN). A short while later the female was seen returning to the nest with food. The next sighting was on **7th June** when a male was seen feeding two juveniles in the grassy area below the track at the north end of the cutting. They were observed for over 20 minutes and in that time the young were seen making short flights around the area and into a nearby tree. At this time a second male was seen flying past from the direction of Sledge Shoe towards Round Hill east.

On **21st June** the male was flushed from the trackside at the north end of the cutting and flew into the dale-bottom and out of view. A juvenile was then seen motionless close to track where the male had been flushed. After a minute or so the juvenile flew off after the male and out of sight. A short time later a female was seen foraging in the dale-bottom. After 10 minutes she flew up the dale side into the north end of the cutting and out of sight. Taking a closer look in the cutting the female was spotted on the track at the south end of the cutting. After a few minutes a juvenile appeared in the same area as the female. The female was then seen shooing the juvenile away along track towards north end of cutting; mysteriously this juvenile had no yellow ring so was not from either the Round Hill west or Round Hill east early nests. The female was then disturbed by a passing walker and flew over the cutting and into the dale-bottom out of view. Looking into the dale-bottom from the north end of the cutting a second female was seen foraging and then flying off towards Sledge Shoe. While this was being observed the cutting female appeared from an unseen location in the dale-bottom and then flying into the north end of the cutting. A closer look in the cutting flushed the female from a nest containing three pulli a day old;

the nest was 44 metres from the first nest on the west side of the cutting and was the first time that a nest had been found on the east bank of this cutting. Calculation suggested that 10 days had elapsed between the first nest fledging and the first egg being laid of the second nest. Allowing three to four days for the second nest being built, this suggests the female had a break of about a week before commencing a second clutch.

On **27th June** four pulli about seven days old were rung with a yellow ring (Ring Letters: DF, DJ, DI & DN). One pulli was noticeably smaller. The male during this time was nowhere to be seen. On **28th June** a quick check was made of the nest and four pulli were seen sitting tight. The female was seen on the track close to the nest. A further visit was made on **2nd July** when the female was seen at the north end of the cutting taking food into the cutting bank in four separate locations; one on the west side and three on the east side. During this time the female was heard making a tuc-tucing contact call and the fledglings replying. The fledglings were located around 50m north of where the nest was, suggesting they could have fledged on 1st July at just 12 days. The female was later seen collecting food from the trackside and on few occasions returning to the cutting with food from the direction of the dale-bottom. The male was noticeably absent at this time. A look at the nest found one pulli dead just behind nest but alongside it (Yellow Ring DJ). The stunted development of the dead pulli suggested it had died when it was 7/8 days old; probably the day after it was rung.

On **5th July** the female was seen in the middle part of the cutting searching for food on the trackside. She popped into the ditch on the moor side of the track and came out after five minutes or so before returning again to the ditch and out of view. Walking past the location she was flushed, flying off over the moor and out of sight. Some 10 minutes later she was briefly seen perched on a clump of heather at south end of the cutting before being lost from view. There were no further sightings of the female and no sign of a male during this period of observation.

There were no further sightings of ouzel activity in the Round Hill west cutting area after this.

5.3.15 Sheriff's Pit

The first sighting here was on **6th April** when a male was seen singing from the newly erected safety fence that surrounds the disused pit shaft. After a short time he flew off over the moor top and out of view. On **15th April** an unseen bird was heard singing in the Sheriff's Pit north area. A short time later while observing the pit from the nearby ruins a male flew from the direction of the dale-bottom on to the pit fence. There was a short snatch of simple song before he then dropped to the ground on the north side of the fence and out of view.

On **18th April** after 20 minutes of observation a male appeared on the pit fence and sang for two minutes or so before flying off over the track towards the dale-bottom and out of sight. An audio recording of the song was made. On **26th April** a male was seen foraging on the moor side of the pit just outside the fence before flying off northwards and out of sight. There was no further sighting until **4th May** when a member of the National Park's Land of Iron team photographed a male on the pit fence. A further sighting was made on **10th May** when a male was seen singing from a clump of heather 25 metres on the daleside of the track just north of the pit and close to where two nests were found in 2017. After a few minutes he flew off in the direction of the dale-bottom and out of sight. Spectral analysis of the song showed it to be the same male recorded singing on the pit fence on 18th April. On **16th May** a male was flushed from the daleside of the track near the pit, flying off in the direction of Thorgill Bank; thought most likely to have been the male that was known to be holding a territory at Thorgill Bank west.

On approaching the pit on **24th May** a male was heard singing from an unseen location close to the shaft. After a few minutes a male flew onto the pit fence and sang a short burst of simple song before then dropping into the shaft out of view. Taking a closer look at the pit shaft the male was flushed from deep inside the shaft, landing on the ground just inside the fence. The male was then seen rummaging around the base of one of the fence posts before flying off over the moor and out of view. Observing the shaft from the nearby ruin on **31st May** a male landed on the pit fence and briefly sang before dropping into the shaft out of view. Approaching the shaft the male was heard singing from the depths of the shaft. After few minutes the male flew out heading north and out of sight; an almost identical situation to the observation on 24th May. This was to be the last recorded sighting of ouzel activity in the Sheriff's Pit area.

Despite frequent sightings of a male in and around the disused pit shaft, there were no sightings of a female at any time throughout the season. The absence of a female during the

breeding season just adds to the mystery at this well used breeding site and raises the question as to whether or not a pair bred there in 2018. However, the presence of a singing male for most of April and throughout the whole of May points to the existence of a territory here and as such Sheriff's Pit has been recorded as a Probable territory.

5.3.16 Sledge Shoe

On **15th April** an unseen ouzel was heard chacking in the dale-bottom at Sledge Shoe. At the same location on **26th April** a male was seen chacking in a tree just north of the public footpath that drops down from the track into the dale-bottom. After a few minutes the bird flew off in a wide circle over the moor before returning to the same tree when it then sang a short snatch of simple song. On **3rd May** a male was seen in the same tree where a male was seen on the 26th. After a few minutes the male flew off to the singleton tree at the south end of the Sledge Shoe territory where it then sang for a minute or so. A short time later a female was seen foraging near the steps that lead down from the track into the dale-bottom. After 10 minutes she flew off into a gully near the tree where earlier a male had been seen singing. A close look into the gully from the daleside edge found no sign of the female, giving the impression that she may have returned to a nest in the gully. The next sighting was on **10th May** when a female was seen stealthily making her way into the same gully but was then lost from view. Taking a closer look at the gully the bird was disturbed while on the ground foraging and flew off up the dale and out of view.

On **24th May** a male was seen chacking just below the track close to the Sledge Shoe footpath. He flew into the dale-bottom out of view. Ten minutes later two males were seen in the dale-bottom just south of the footpath. One flew to where the earlier bird had been seen the other flew off in the direction of Round Hill west out of sight. On **7 June** a male and a juvenile were seen flying high towards Round Hill west from the north end of the Sledge Shoe territory and landing in the Round Hill west area and out of view. Later in the day a male was seen singing in a tree at the south end of the Sledge Shoe territory. A while later a male was seen perched on a rock close to the Sledge Shoe footpath before then flying off into a rocky area close to the gully where a female had been seen going into on 3rd May. Later in the day, just north of the Sledge Shoe footpath, a male was seen on the ground 20 metres below the track singing. He sang for over five minutes before flying off over the dale edge out of sight – audio recording made. Spectral analysis of the recording showed it to be the same bird recorded at Round Hill east on 10th May singing in a tree just below the track close to the nest site. On **21st June** two females were seen foraging in the grassy area below Round Hill west. One flew off northwards towards Sledge Shoe the other into the north end of the Round Hill west cutting; where a second nest had been located (see 5.3.14).

There was no further activity in the Sledge Shoe area after 21st June. Although no nest was found the frequent sighting of a male singing during the later part of April and throughout May and the early part of June, as well as the presence of a female on several occasions during May and June, lead to the conclusion that an early and possibly late nest had been attempted.

5.3.17 Thorgill Bank quarry

On **16th May** an unseen ouzel was heard singing from a location close to Thorgill Bank quarry; the male singing continuously for five or so minutes. A search of the quarry and surrounding area found no trace of the bird. On **31st May** a male was seen on the quarry cairn singing for around 15 minutes before dropping to the ground out of view. Later in the day a male was seen again on the cairn singing. Analysis of the sonogram of the bird's song pointed to it being the same ouzel recorded earlier in the day at Hob Crag quarry, suggesting it was most likely an unattached male roaming the area looking for a female (see 5.3.7).

The next sighting was on **13th June** when a male was flushed from the quarry. It first flew off eastwards before turning back and flying past the quarry westwards out of sight. This was the last sighting until **5th July** when the moor keeper reported seeing an ouzel immediately above the quarry close to the track. There were no further sightings after this in the quarry area.

5.3.18 Thorgill Bank west

The first sighting at this location was on **22nd April** when a member of the Scarborough Field Naturalists reported seeing a male and female feeding close to the track some 300 metres west of the old sheepfold at Thorgill Bank west. On **5th May** a male was seen in the Thorgill Head

area, 500 metres west of the sheepfold, flying up the gill from the dale-bottom towards the head of the gill before dropping to ground 50 metres before the track. On **16th May** a male was flushed from the trackside 200 metres south of Sheriff's Pit, flying off high towards Thorgill Head and out of sight. The next sighting was on **31st May** when a male was seen on the wall of the sheepfold. The bird remained on the wall for five or so minutes before dropping to ground below the wall and out of sight. Later in the day a male and one juvenile (possibly two) were flushed from the trackside 200 metres west of the sheepfold. Both flew off down the dale before dropping to ground some 100 metres below the track out of view. A while later the male was seen in the same area on a clump of heather, giving the impression that he was keeping watch on the juveniles hidden in the heather nearby. There were no further sightings in the Thorgill Bank west area after the end of May.

5.4 Breeding Productivity

The low number of breeding pairs this season was reflected in the fewer nests that were located; just four, one on the east side and three on the west. All nests used man-made features, three in cuttings and one in a small trackside quarry. Three nests, Reeking Gill cutting Round Hill west and Round Hill east, were early nests with the latter recorded as being predated at the chick stage. The pair at Round Hill west had a late nest 40 metres from the first nest but on the east side of the cutting; the first time this side of the cutting had been used in the 20 years of the study. Overall productivity for 2018 was fractionally below the 17-year mean of 3.10 (see Figure 12) with the mean number of fledged young per laying pair being 3.00; the same as 2017. This is the sixth year since 2012 that below average productivity has been recorded and is most likely a consequence of early nest predation and fewer late nests.

Most Ring Ouzels will attempt a replacement nest if the first fails, though this may not be for a week or more later. As a result it may be well into June before the young from this nest fledge - assuming all goes well and the replacement nest is not predated. For most birds this would make it too late in the season to start a late second nest; the breeding season ending for most Ring Ouzels around the first week in July. In effect, for those birds that had their first nest predated, they would have run-out of time and the breeding season for them would be over with at best just one successful clutch to show for the season.

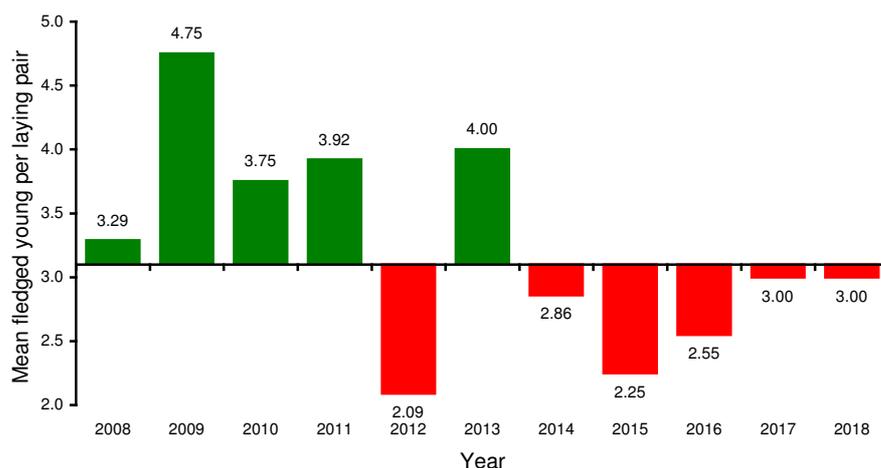

Figure 12: Mean fledged young per laying pair for Rosedale and other areas of the North York Moors between 2008 and 2018 relative to 17-year mean of 3.10

Figures 13 and 14 below show the annual hatching and fledging success for first and second nests. Hatching success looks at all the eggs laid and the percentage of these that hatched. Similarly, fledging success looks at all the eggs laid and the percentage of these that hatched

then successfully fledged. A value of 1.0 would indicate 100% success whereas 0.5 would indicate 50% success - that is only half of all eggs laid hatched or fledged.

In 2018 83% of 1st (early) nest eggs hatched with a half, 50%, fledging. Of the 2nd (late) nests monitored, 87%, of eggs laid hatched with three quarters of these, 75%, successfully fledging.

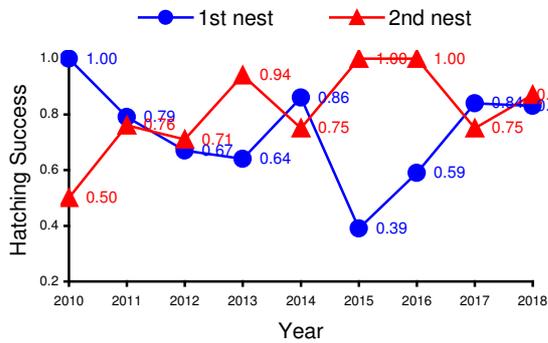

Figure 13: Annual first and second nest hatching success for the Rosedale area of the North York Moors between 2010-2018. Data from Annex 3, Table 1, for known and likely values.

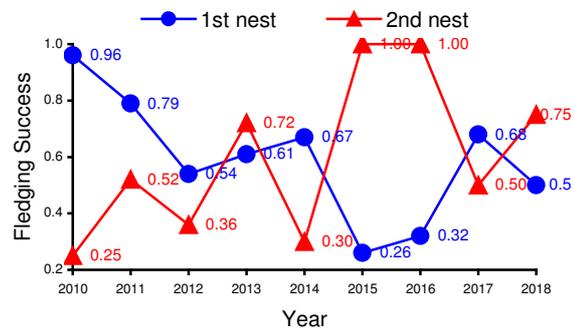

Figure 14: Annual first and second nest fledging success for the Rosedale area of the North York Moors between 2010-2018. Data from Annex 3, Table 1, for known and likely values.

5.5 Late:Early Territory Occupancy

Most bird publications describe the Ring Ouzel as usually being a double brooded species. As not all pairs will have a second nest and fledge a further clutch, one of the concerns is what impact this has on population numbers. For a short lived species, three years for the average Ring Ouzel would be a good age, having a second brood may be important in sustaining or expanding the population.

The method used to determine early and late occupancy was to divide the number of territories that were occupied by pairs after late May (late territories) by the number occupied before late May (early territories) - see Annex 5. The graph at Figure 15 below shows the ratio of late to early occupancy between 2008 and 2018 relative to 11-year mean of 0.54; suggesting just over half, 54 %, of Rosedale Ring Ouzels have on average a second nest. Also to note is the below average occupancy of three of the last five years.

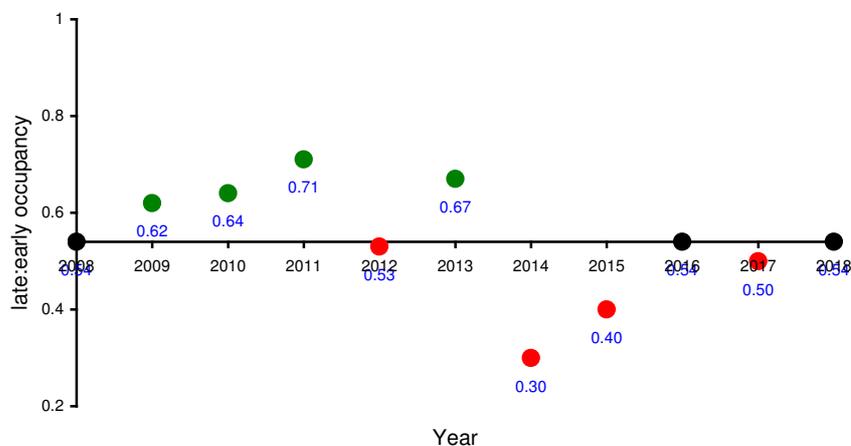

Figure 15: Annual ratio of late to early territory occupancy for the Rosedale area of the North York Moors between 2008-2018 relative to 11-year mean of 0.54

5.6 Nest Aspect

The aspect of a nest is the compass bearing that the nest entrance faces and is the direction the adult birds are seen to use most to enter or exit the nest. It is likely that the topography has a strong influence on nest aspect in Rosedale. The main dale runs NW to SE and on the east side, where it might be expected that more nests would face west, the two main offshoot gills of Reeking Gill and Sturdy Bank and the quarry at Dalehead seem to present fewer opportunities for nests to face this direction. Likewise, on the west side of the dale the quarries at Matty Carr and Hob Crag predominantly face east as do the heather banks at Blakey Lion, Dalehead west and Round Hill east and south. Only at Round Hill west where the disused railway cutting has ideal heather banks for nesting, with a choice of either east or west facing aspects, do Ring Ouzels mainly prefer the side of the cutting facing east – in 2018 a pair had a late nest on the east side of the cutting, the first to be recorded on this side. At Sheriff's Pit where the four sides of the shaft entrance are aligned either NE, NW, SW or SE, the preferred aspect is either SE or NE; though this has probably more to do with the suitability of the shaft sides for nesting. The graph at Fig.16 for all nests in the Rosedale area (data from 1999 to 2018) clearly shows a strong bias to an easterly bearing, with the north-east quadrant being the predominant aspect. For reasons that can't be explained, the south-west quadrant seems to be equally as prominent as the north-east quadrant for second nests - see Fig. 17 and 18. What is clear from all three graphs is that few nests are built with an aspect in the north-west quadrant. Whether this is a deliberate move by Rosedale Ring Ouzels or not is uncertain and is an area of study that needs further work.

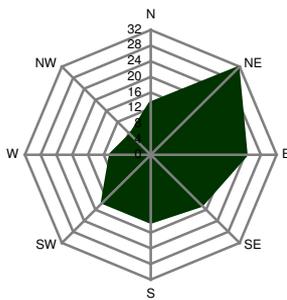

Figure 16: Nest aspect of all nests in the Rosedale area.
Data from Annex 4, Table 1. n=140

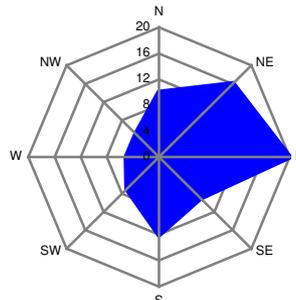

Figure 17: Nest aspect of first nests in the Rosedale area.
Data from Annex 4, Table 1. n=84

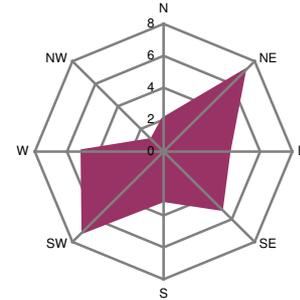

Figure 18: Nest aspect of second nests in the Rosedale area.
Data from Annex 4, Table 1. n=34

In Figures 16 to 18 above the intercardinal points NNE, ENE etc. are not shown. This is done to smooth the graphs and remove the spikes that would be generated if all 16 points were displayed. For each of the eight intercardinal points shown in Annex 4, Table 1, the value (the number of nests with that aspect) is halved and apportioned to each adjacent cardinal point. For example, if the number of nests having an intercardinal aspect of NNE was four, then two would be added to the N cardinal value and two to the NE cardinal value. If the ENE aspect had three nests, then one would be added to NE and one to E. None of the intercardinal points recording just one nest are counted.

5.7 Nest Elevation

Due to the low-lying nature of the terrain, most Ring Ouzel territories in the North York Moors are confined to a narrow altitudinal band lying between the 250 and 400 metre contours. The highest point on the North York Moors lies at 454 metres on Urra Moor and in Rosedale just over 400 metres at Rosedale Head. In the Rosedale area the lowest nest was found at Loskey Beck at 218 metres and the highest above Reeking Gill at 392 metres; with the mean and median altitude being 324 and 331 metres respectively. Just under 70% of nests found were in a 50 metre band between the 300 and 350 metre contour. The restricted altitudinal band for breeding Ring Ouzels may point to climate change being a potential problem in the coming years for the North York Moors population. Figure 19 shows the elevation of 151 nests recorded in the Rosedale area of the North York Moors between 1999 and 2018.

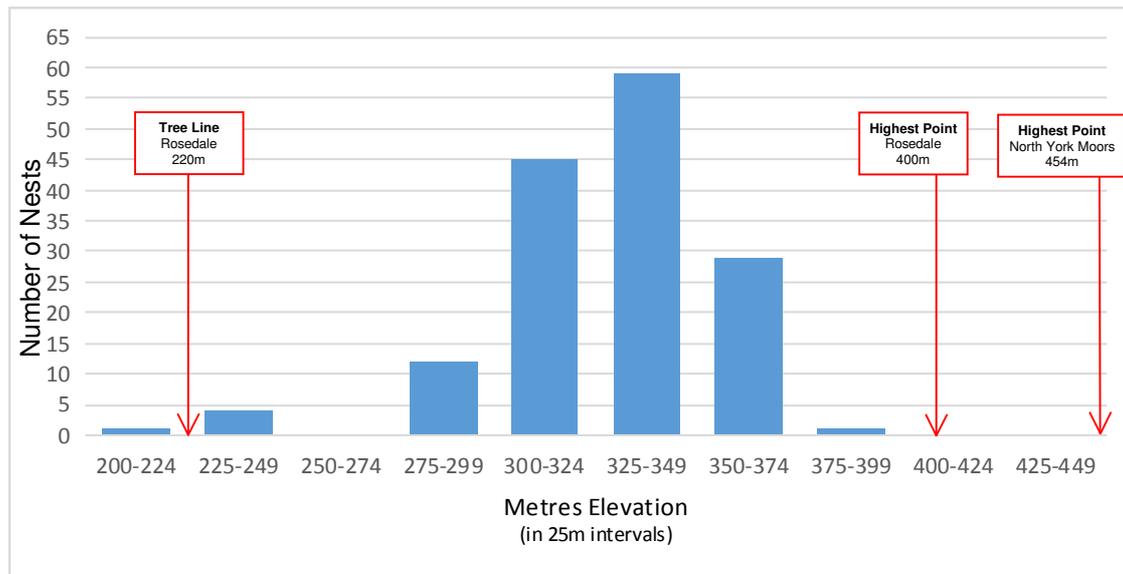

Figure 19: Elevation above mean sea level of nests recorded in the Rosedale area of the North York Moors between 1999 and 2018. Data from Annex 4, Table 1. n=151

5.8 Spring Passage Migrants

Fennoscandia Ring Ouzels on passage are seen most years in Rosedale and the wider North York Moors during April. These birds stop off to feed for a few days before commencing their onward journey to Scandinavia. On **9th April** a pair seen feeding at Nab Scar on the east side of the dale may have been local birds but at least five more near by were probably on passage. On **11th April** over 40 were seen on the south side of Roseberry Topping with a further five sighted above Kildale - both locations are in the North-West corner of the Moors. Again on **15th April** 10 were reported feeding on the south side of Roseberry Topping.

There were early sightings on the Yorkshire coast of a male at Spurn Point on **12th January** and a little further north a female at Aldbrough on **22nd February**. In addition, the Teesmouth Bird Club recorded sightings at the following places along the coastal fringe of Cleveland: South Gare a single bird on **6th April** and two on **14th April**; five birds at Hummersea on **7 April**; two at Hunley Hall on **14th April** and five at Warsett Hill on **15th April**.

An unusual sighting of what was likely to be an over-wintering Ring Ouzel was reported by several local birders at Brompton-by-Sawdon (SE942821) just west of Scarborough. The first sighting was on **14th January** when a lone male was seen feeding in a meadow near the church. Further sightings, of what was assumed to be the same male, were seen in the same location on **20th January** and **1st, 4th and 25th February**. There were no further sightings after this.

5.9 Late Summer Activity

There were several reported sightings in August and September. The first on **26th August** when five were seen feeding in Rowan trees above Medd's Farm on the west side of the dale. Two were seen flying in a northerly direction over Blakey Swang on **28th August** and two above Nab Scar on **30th August**. On **15th September** over 15 were seen at Gill Bank above Thorgill on the west side of the dale.

6. ACKNOWLEDGEMENTS

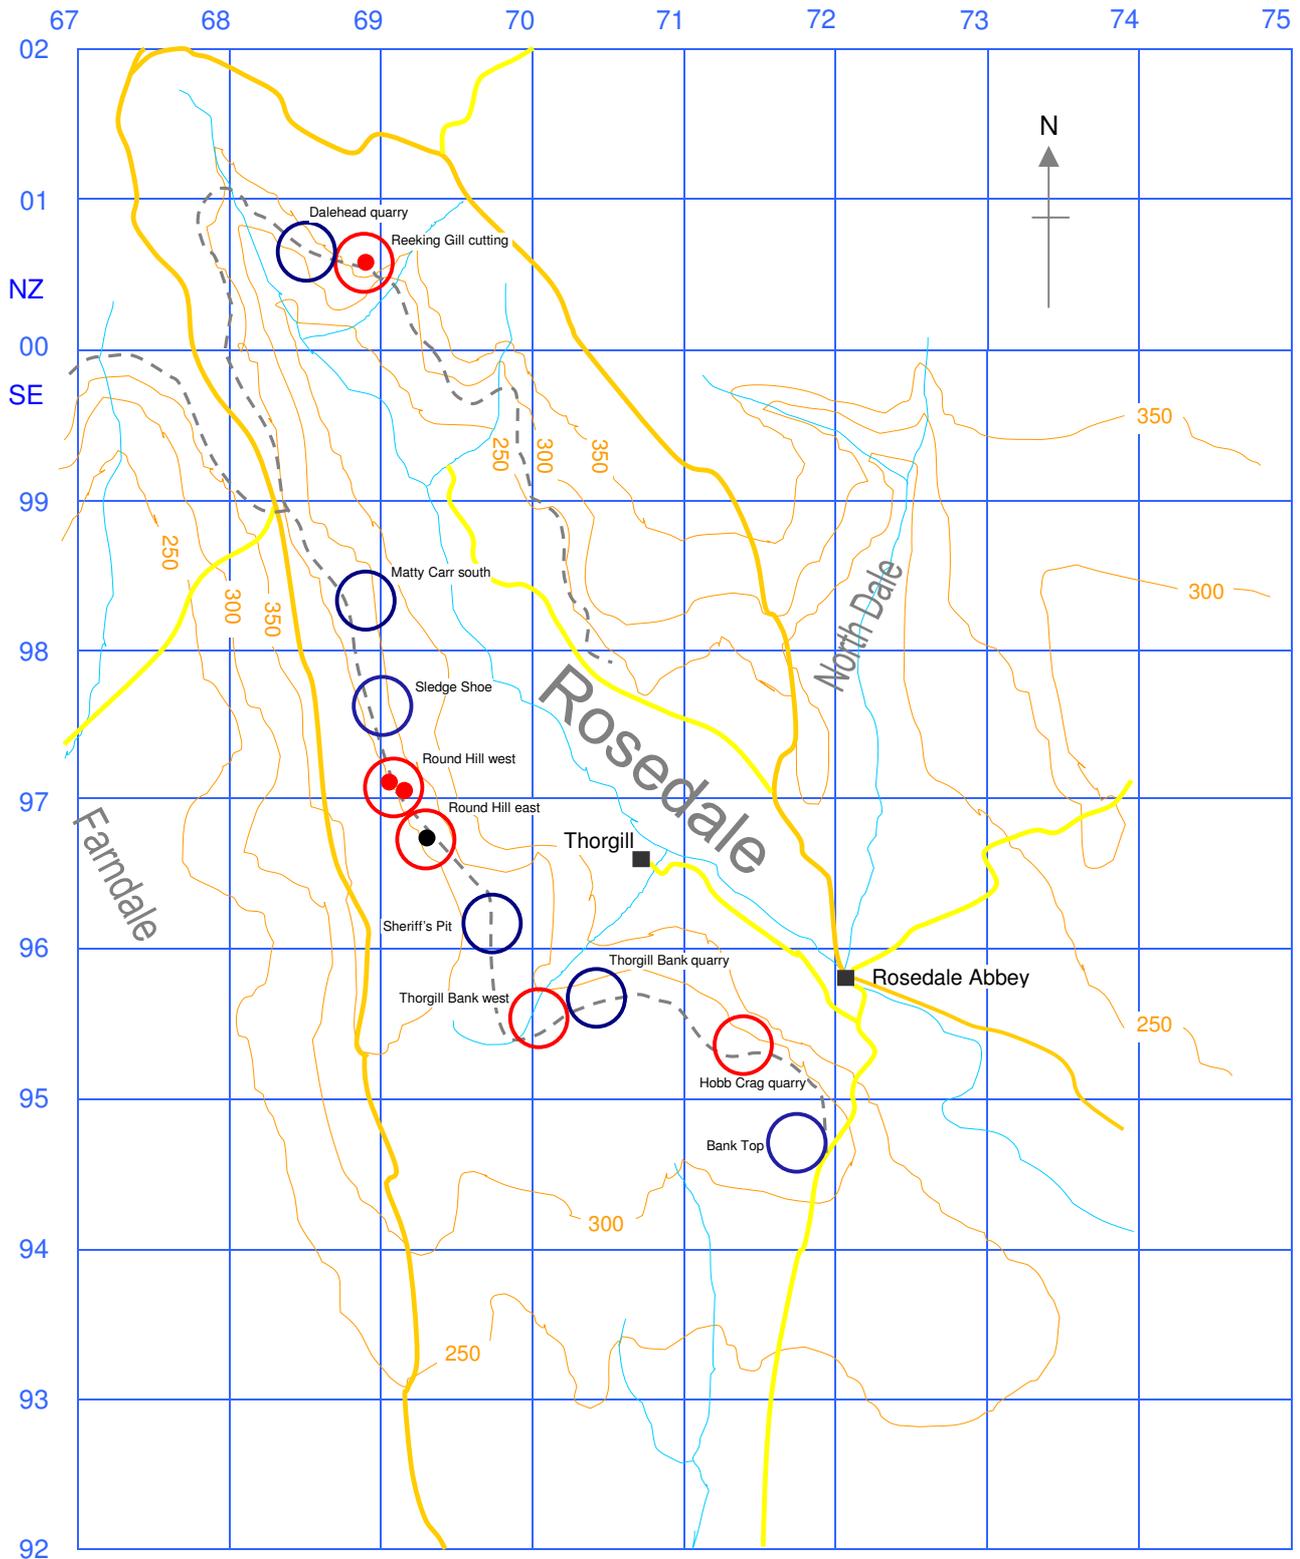

The authors wish to acknowledge the support of Spaunton estate owner, George Winn-Darley, head-keeper George Thompson and under-keeper Anthony Orr. Also Tom Denney, Geoff Myers, Robert Stark and Eric Wood. Our grateful thanks to all of them.
